# Humans as part of living systems

"I try to come once a month at least," said Tendai. "Do you know that this hill was once a sacred site? Mbuya and a few other in this area are trying to revive it as a sacred site." "What does a sacred site mean?" I asked Tendai.

"I'll tell you one day. I'm still learning myself. For now, it's a place where I can come and be with Nature and imagine how our ancestors lived for thousands of years. That nyimo you're eating is part of that history. It has nourished many generations of our ancestors. When you eat it you're eating out history. When you pick fruits from the indigenous trees like we did on the way up here, you're doing what people have been doing here for centuries."

We were high up and could see far into the distance. There were many small hills like ours, mixtures of boulders, smaller rocks, trees and many other plants. Ours was the highest. I looked admiringly at my cousin-brother, Tendai, a man now while I was still a boy. Above his head, I noticed a bird high in the sky, like it was floating. I pointed and asked Tendai, "What's that?" "That," said in a solemn voice, "is your great, great grandmother keeping an eye on us." My jaw fell open. "Really?" His face looked serious, and then he smiled. "Don't believe everything I tell you. It's a hawk looking for prey. But I like to think of it as our great, great grandmother keeping an eye on us. And perhaps it is, you never know."

One with the soil, one with water, one with air; one with creation.

A grain among multifarious many;

a drop in placid pools, rushing rivers, crashing waves;

a mere microcosm in the atmosphere.

Breathe deep, drink long, cup sand in hands with fingers splayed to sift the particles;

celebrate oneness.

From dust, to dust, of dust;

& dust we've become for the soil that shapes us has died;

played out and poisoned.

And I, one with the earth, suffer genocide.

Yet, sunrise melts frost and ice.

Hidden, spring smiles and waits.

"We are showered every day with the gifts of the Earth, gifts we have neither earned nor paid for. For the Earth to stay in balance, for the gifts to continue to flow, we must give back in equal measure for what we take." – Robin Wall Kimmerer

In the teachings of my Potawatomi ancestors, responsibilities and gifts are understood as two sides of the same coin. The possession of a gift is coupled with a duty to use it for the benefit of all. A thrush is given the gift of song—and so has a responsibility to greet the day with music. Salmon have the gift of travel, so they accept the duty of carrying food upriver. So when we ask ourselves, what is our responsibility to the Earth, we are also asking, "What is our gift? Among the most potent of these is gratitude."-- Robin Wall Kimmerer

Some questions put to various people from different contexts & their responses:

1. How does climate change affect you personally as a young person, a woman, a faith leader, a home-owner/householder, a family?
  - Members of a local church had the following to say: David McConnell, a young unmarried man: "It affects me as a temporary visitor to planet earth most the same way it will affect us all eventually, although as usual the most vulnerable will bear the brunt." Paul Roberts, a retired civil engineer who has worked throughout his lifetime in water resources management & development: "It doesn't affect me a great deal as it is difficult to quantify what is due to climate change, resource over-utilisation, inept management, etc. The effects of climate change are often exaggerated in the media. Some resource shortages, like water & electricity, may be influenced by climate change."
  - A young family member who is a high school teacher & her husband who is a fashion designer said: "It doesn't necessarily affect us as householders in a very direct way. It affects us in the same way it affects the world in terms of impending doom when it comes to whether or not the earth can sustain us."
  - A black woman who is a Minister in the Presbyterian Church said: "I'm a woman serving in a rural area where many church members are unemployed. They depend on their small gardens to provide food for their children. Droughts and water problems affect

our lives so badly. Some are cattle farmers. Climate change is a problem. They grow their crops seasonally. Due to climate change that confuses their schedule."

2. What do you feel you can do to mitigate or adapt to the effects of climate change?

- Members of a local church in Pretoria said the following: David McConnell (a young single male) "The key is that every little change makes a difference. I've reduced the amount of meat I consume, with production & feeding of livestock being the greatest contributor. Another key is for people not to get frozen into doing nothing, eg because giving up meat completely is too extreme ... to start with meat-free Mondays already makes a difference ... then move from there & be conscious of wherever else you can make an impact such as paying to offset the carbon for your travel; Bokashi kitchen scraps; use energy sparingly, etc." Neil Burgess (retired engineer) says: "My father said tarred roads, paving & house roofs where there was originally veld would change the climate. So home-owners should consider the colour of paint used on roofs. New houses could be built with solar roof tiles instead of concrete, with separate solar panels on top. A neighbour has whirly hot air extractors on his roof to help cool the house in summer, but they spin even in winter. Solar geysers are another option (See all the matchbox houses alongside Marlboro Gautrain station, each with a solar geyser). Electric power stations using concentrated solar heat with overnight storage would be good (There are a few small ones in SA). Cooking with a microwave oven uses less energy consumption due to the speed of heat transfer. We should use modern efficient low-wattage globes for lighting. It would be good to drive an electric car (Have you seen the recharging point provided in a corner of the Menlyn parkade?) I wish the mechanical & chemical engineers would organise a breakthrough for safe ammonia-free type cooling for fridges & air-conditioning (It could be solar-powered, but ammonia is poisonous). Brilliantly lit offices at night are unnecessary. Americans & Europeans light only the surfaces of their desks." Paul Roberts retired civil engineer who worked in water resource management & development says: "Mitigation measures that we implement at home as a couple include recycling, moderate use of resources, solar heating of water, purchase of local produce as far as possible." He adds the following: "Various remedial measures have been proposed (& partially accepted by many countries) to combat climate change. I am in full agreement that we need to contain emissions (pollution) of various kinds. What really concerns me is that the main driver for the increase usage of the world's resources has been almost totally ignore & this is one of the factors which should be examined! The main driving force for increased consumption of resources is population growth as well as rising living

standards which increase the per capita consumption. In the 1980's when I was in the Department of Water Affairs, I was asked to determine the maximum population that South Africa could sustain based on its available water resources. We determined a figure of 80-million - note that we now are around 60-million & I can see that our water systems are already highly developed & under stress. There is not a huge remaining potential for further development of water resources. Desalination of the sea is a possibility, but requires an enormous energy input plus is very costly.

"I attended the 2nd World Water Forum in 2000 in The Hague & noted that absolutely no mention was made of population pressures in the resulting Ministerial Declaration. I have undertaken numerous water demand studies in SA & the main drive is population. Many people argue that the rich use a greater per capita share of resources, but fail to consider that poorer communities also aspire to higher living standards, hence greater resource consumption. A good example of this issue is the question of sanitation. From 1994 the Dept of Water Affairs instituted a Basic Water Supply & Sanitation initiative. Initially the parameters were: Water supplied in community taps not more than 500 m apart; & Basic sanitation was via VIP toilets (Ventilated Improved Pit latrines). Currently because of various problems, rising expectations & community perceptions, the drive is towards: Water delivered to individual houses; & Flush toilets (which require more water plus other resources). Such changes demand on the level of services must always be anticipated in resource planning.

"Population limitation: I have yet to ascertain why the issue of population limitation has not fully entered the climate change debate. It is probably because it is politically & socially very sensitive. Lester R Brown in his book 'Plan B: Rescuing a Planet under Stress & a Civilization in Trouble' 2003 pays a lot of attention to this issue & considered that the world population should be stabilised at about 7.5 billion people using various economic & social incentives & measures. In 2020 the world population was 7.8 billion & there are projections that it will exceed 10 billion by 2050. It is clear that current efforts to contain population growth have not succeeded & the issue needs to become part of the international debate on climate change."

- Young female family member (teacher) & her husband (fashion designer) say, "Because we don't really directly feel the effects (or at least, it's not something we focus on), there's not much we do to adapt to the effects. We're also not the greatest at being aware of it, but we do eat a lot less meat because that has a massive impact on the environment. We also try to conserve resources in terms of electricity and water as much as we can."

- Black woman who is a Presbyterian Minister in a rural community says, "When they experience problems with their farming, it also affects the income of the church. So those who are in the townships need to provide food parcels to the needy. Even our church garden doesn't produce as much. We used to get some vegetables from it for the needy & to sell some with aim of generating income."

### 3. What do you personally feel about it?

- Members of a local church in Pretoria: David McConnell (Young single male) says, "I'm hugely concerned. It needs an economic resolution to a problem created by the current model; that along with plastic pollution being my chief areas of focus when trying to make a difference in my own space." Neil Burgess (retired engineer) says, "Humans are reckless in their pursuit & exploitation of technology for profits. How long did it take to lessen the smoke output from factory chimneys spawned by the first industrial revolution? Using electric power in the workplace & in homes first needed many deaths before safety earthing & "earth leakage" protection was introduced. Millions of cars were sold with primitive inefficient polluting internal combustion engines before we got the better engines of today & the eventual appearance of electrically powered cars, buses & trucks." Paul Roberts (retired civil engineer who worked in water resources management & development) says, "I feel ambivalent about the magnitude & impact of climate change. The impact of population size needs to be a major issue in the climate change debate & the determination of mitigation options. Population limitation should not be enforced but encouraged by incentives & economic disincentives."

"Is climate change real? We know that over the ages there have been a number of major climate changes that were certainly not influenced by human activities. We have limited recordings of the various climatic variables. In SA river flow records go back for about 100 years while rainfall records are several hundred years long. In some places such as the Nile River we have flood peak level records which go back several thousand years. Some records can be extended by other means such as tree rings, sediment deposits, ice in the polar regions, etc.

"What does concern me is that currently every extreme event such as a flood or a wildfire is ascribed to climate change. In many cases, such events still fall into the general pattern of probabilities of extreme events such as floods. It is to be expected that as the monitoring time gets longer so we will experience further extreme events. This is similar to athletics records where as time goes on world records keep getting broken!

"An analysis of SA hydrology does not show any major deviation from expected patterns. On a global scale experts have used other parameters such as glacial reduction, increase in cyclone activity, global temperature increase, etc as indicators of climate change & ascribed these all to the cause of the activities of humankind. It is very difficult to separate natural causes & anthropogenic ones. It is fashionable to ascribe most extreme events as being caused by climate change as it is also a popular route to generate project funding!"

- Young female family member (teacher) & her husband (fashion designer) say: "We both acknowledge it's a very real crisis, but I don't think it's one that we worry about (or at least talk about) that much. If we're brutally honest, we're probably not as actively concerned & focused on it as we should be."

It's clear to me from these responses & general conversations with people over the past six weeks or so, that the younger adults are showing far more concern about climate change, but only some are actively taking steps to mitigate it. The retired engineering shows a typical resistance to the realities of climate change & standard means of justifying this resistance. The lady minister in a rural congregation expressed concerns about the reality of the impact on the local community within which she serves. These are all issues that might need to shape the work in preparing guidelines on climate change.

- Neil

# A different take on climate change

"Our rain used to be more reliable," Amai Moses said to me when I visited her many years ago. We were seated in her round thatched kitchen, whose walls were made of mud. The smoke drifted up and out through the roof. The inside thatch was black from years of smoke passing through. A few maize cobs hung from the rafters, grown to eat green mealies not for grain. The smoke kept them free of weavils. This was the seed for next year. On a shelf were many jars all filled with different seed. I counted over 30. Amai Moses was one of the few seed custodians left in the area. The government's relentless drive to push 'modern' farming had sidelined people like Amai Moses. Mixed and diverse cropping was considered backward and unpatriotic by the government extension staff. So Amai Moses did her cropping in a field hidden from public view.

"That was when we had more trees. Trees bring rain. Yet you can't receive the master farmer award if you have even one tree in your cropping areas," continued Amai Moses. Was she opening up to me because I was an outsider who had shown interest in her mixed cropping fields? Who didn't think she was 'backward'? We spent a long time discussing all her different crops and the varieties of each that she grew and what each was good for. That was over 30 years ago. Since then tree removal has speeded up all over the country.

I came away thinking about Amai Moses' remark on trees. Did cutting of trees really affect local rain? Wasn't rain affected by much bigger forces? I puzzled over this for many years and it was only when I learnt about the role of the small water cycles, especially for places well inland from any ocean, that I began to really understand the role of trees, and in fact all vegetation, in the climate. Understanding (to some extent!) the part the small water cycle plays has been one of my biggest insights into climate change and their potential to help the climate cool the Earth and build local resilience. Amai Moses knew that - we underestimate indigenous knowledge to our peril.

"Professor Millán Millán is a strong, often lone, voice within the scientific community, arguing that changes in land use have profound effects on climate patterns. ....His work points to a clear connection between landscape alteration and climate, a subject generally absent from high-level discussions about climate change, which typically focus solely on parts per million of carbon dioxide in the atmosphere." (P.178, *The Reindeer Chronicles: And Other inspiring stories of working with Nature* - by Judith. D. Schwartz)

Millán Millán found in his studies that "Water that evaporated from the Mediterranean Sea would fall at higher elevations some sixty to eighty kilometres inland - the moisture climbing up the slope, as if on a staircase, via the orographic effect that lifts and then cools the air mass so that it condenses to form clouds and rain. The culmination of several land-use changes over time

- deforestation, the draining of marshes for agriculture, construction on wetlands, shrouding soil with houses, asphalt, and concrete, and an increase in wildfires - has resulted in less evapotranspiration along the sea's path. On its own, the vapour carried from the Mediterranean was never sufficient to elicit rainfall, he says. The moisture rising from the land, emanating from moist soil and transpiring from vegetation, was the trigger that made it happen." (P. 181, The Reindeer Chronicles...). That last sentence strikes such a chord with what seems to be happening here in Zimbabwe. Often the clouds build up and build up but then it fails to rain; perhaps also there's a lack of pseudomonas bacteria from tree leaves to act as a nucleus for raindrops to condense on.

(It would be very good if we could do an interview with Millán Millán for the BFG, or he writes something; his research over years illustrates this connection between land use and climate change)

There has been a fundamental failure in the way in which the idea of climate change has been communicated, based on a misunderstanding of human cognition, social and behavior change and the systematic nature of the challenge. Rare is an organization focused on motivating individuals, their communities, and their local leaders to adopt behaviors that benefit both people and nature. Check out their website [www.rare.org](http://www.rare.org). They might be interested in helping develop this guide.

We often refer to material objects as "priceless" but not natural resources. Nature is seen as a commodity to be bought, sold and traded.

Water Connects all things,  
brings movement, gives life

Without water , there is no life and there will be no life.

Water is like the lifeblood of the earth.

I wake in the morning and stumble out of bed, put the jug under the clay filter and turn on the tap. I listen to the sound of the water hitting the bottom of the jug. When it's full I pour water into the kettle, another liquid sound. Switch on the kettle and more water noises begin, as it takes the water to boiling point, which here at 1,500 meters above sea level is significantly lower than at sea level.

I fill the Italian coffee maker with hot water and coffee grounds and put it on the stove. In a few minutes it's gurgling. I pour the dark black, almost thick liquid into our two cups, dilute it with more boiled water and some milk. We sip the coffee together, listening to the sound of water on the tin roof, a steady pattering that has been going for most of the night.

With my coffee drunk, I put on waterproofs and go out to pump water from the tanks on the north side of the house into the big storage pool. Water from the south side roofs goes straight into the pool. The 5,000 litre tanks are full and will soon overflow if I don't empty them. We try to catch and store every drop from our roofs during the rainy season.

The rain eases mid-morning and the sun comes out as I walk around my small dryland cropping areas. Everywhere, water is glistening and sparkling on leaves. The plants all glow, water-content. The rains have been good this year.

There's nothing I can do today in the cropping areas today, as anything I do will damage the water-laden soil. Instead, I take my granddaughter for a walk on the Domboshawa hills, She spends hours playing in the rock pools, filled with water at this time of the year. I sit and enjoy the view, sitting in the shade of a tree growing out of the rock. I also marvel at the yellows and oranges of the lichens that Domboshawa is well known for, almost psychedelic. I see clouds building in the distance, another rainstorm likely in the late afternoon. We head home before any danger of lightning, not a good idea being exposed on a big, open rock.

The storm breaks as we arrive home. We rush inside getting very wet in the short distance between car and kitchen door. Now it's impossible to hear each other with the sound of the rain pummelling the tin roof. Lucky that I emptied those tanks in the morning. I have a shower and enjoy the water warmed by the solar heater flowing down over my body. The water removes both dirt and any stress. From morning until night, water connects my days in a myriad of ways.

Soil sponge is the  
infrastructure of life

It is becoming increasingly apparent that the main drivers of life on Mother Earth are microbial. Perhaps the difficulty in recognising this is because without a microscope we can't see this incredibly complex world. Unfortunately, probably because we can't see it, we have often brought devastation to this microbial world. Most of our practices wreak havoc on the complex world of microbes. And we just keep doing them. And then, because of the havoc, in order to try and deal with it we turn to synthetic fertilisers, which give some relief apparently, like a headache pill. But these highly soluble synthetic fertilisers wreak more havoc on soil life. When you really stop to think about it, it's crazy what we've been doing and what we continue to do, as if there was no future.

And then because we grow plants deficient in a full spectrum of nutrients, they get sick and so we spray more synthetics, often quite toxic. It just gets worse. And we do diplomas, degrees, Masters Degrees and PhDs in all this too. Training people to wreak havoc on soil life even more effectively. Sometimes I shake my head in disbelief.

But we can start to bring things back. And one of the places we can go to in order to help us is those natural places where soil life still thrives. Here microbial life has flourished for millions of years. That microbial life is full of indigenous knowledge, memories, that go back into aeons of time. This is the knowledge that knows how to look after the soil. We can tap into that life, multiply it up and start to apply it in our farming areas so that we can gradually bring life back to all the nearly-dead soils everywhere.

"According to the USDA-NRCS, the most conservative estimates suggest that every 1% increase in soil OM will help soils hold up to 20,000 gallons more water per acre (Bryant 2015)."

# Trust Nature and Trust Each Other

"Where's the evidence that natural farming can feed the world?" This is a question thrown at those developing alternative farming systems to the conventional ones. These conventional ones generally use external chemical inputs and practice monocropping. Natural farming aims to follow the way nature works. My answer to the question above is: "We have millions of years of evidence in the way nature works. Go into a natural situation and see how healthy that situation is. Is that not evidence enough? We need to start trusting nature instead of trying to control nature, as has been the overriding tendency in the last century or so." As soon as we take that step of trusting nature, it begins us on a path to farming and use of land in general that has huge bountiful potential, just as nature is bountiful.

<https://www.youtube.com/watch?v=SYgjuMtGQtc>

Earth is always trying to fix itself. We are not alone if we are trying to fix it.

Doing what we can is not a useless waste of effort. Many naysayers think that you are just wasting your time unless you are doing something really big to help slow climate change. I don't think that is true. Little things add up.

# Interdependence, Interconnectedness and Community

As I write this, looking out of my window at the food garden I'm lucky enough to have, I sense much life beating out there, way beyond my comprehension. I don't take mind enhancing drugs but sometimes as I walk around my garden it feels like I imagine that might be.

There's so much life going on that it's overwhelming, and yet, I only get this tiny glimpse of it, the lizards scurrying away, the bees buzzing in the flowers, the spiders carrying their eggs in haste to safety, the snails making their way slowly across the path, the big centipedes, all over the place, moving a little faster than the snails, their concertina of legs flowing in a wavy rhythm of their own, curling up at a touch, and the birds singing from every tree, a symphony that happens each early morning, and to a lesser extent throughout the day - and yet, all this is but a tiny part of the life that's going on, most of it happening underground. Life, given a chance, beats incessantly, everywhere. The complexity of it is as difficult for us to grasp as the concept of infinity. We can only learn to tune in.

Evidence shows that we are all more connected when we go outside and interact with our natural surroundings. (See Rosa, C.D., & Collado, S. (2019). "Experiences in Nature and Environmental Attitudes and Behaviors: Setting the Ground for Future Research," *Frontiers in Psychology* 10, no. 763, 1-9.)

An invitation: take a break from what you are doing and walk outside. Look at and listen to the world around you.

Last year during the pandemic, I spent more time outside. It was a way for me to feel relaxed and connect to the nonhuman world around me. I watched the different seasons ebb and flow. I began utilizing community science apps to monitor and map plants and animals living around me. The apps have made it easy to notice so much more about the natural world.

Many modern religious beliefs are based on nature worship--theism, panentheism, pantheism, deism, polytheism, animism, totemism, shamanism, paganism, and sarnatism. I find that fascinating.

I often have to remind myself that just because the industrialist culture I live in emphasize quickness and brevity doesn't mean that I have to live that way. I force myself to slow down and look around. As a result, I feel more connected and living congruously with the nature of the Earth. It has made me appreciate all that is around me and do things to give back to the planet, like not buying products with a lot of packaging, picking up litter, and cutting back my energy use.

People expect the government to act but the government thinks people don't care about climate change enough. We need to break 'climate silence' and normalize discussions on the issue.

# Inspiration to Radical Change

Every one of us has an incredible opportunity to help our planet restore itself. Small acts can lead to big changes. However, we are- as George Marshall sets out in his book, *Why our brains are wired to ignore climate change*, in many ways 'wired' to deny climate change.

Beauty lurks in unexpected places, sometimes sharing space with gritty urban parking lots. But have you ever noticed that plants are always busting through concrete and growing out of the tiniest spaces? I admire their tenacity and adaptability.

"Mother Earth needs us to keep our covenant. We will do this in courts, we will do this on our radio station, and we will commit to our descendants to work hard to protect this land and water for them. Whether you have feet, wings, fins, or roots, we are all in it together." --Winona LaDuke

We are changing the climate, but it's not yet changing enough of us. Climate change must move from being a scientific to a social fact. We need everybody to feel a personal sense of urgency. Right now people don't see themselves as part of either the problem or solution. Science is like a broken record and is translated into a generic call to action. There is climate fatigue and people aren't enthused by the issue- at least not enough to respond in a way that reflects the urgency and magnitude of the challenge.

Climate fatigue, a social silence, and stealth denial is a deadly cocktail. A radical reframing is required.

We can't separate questions of economic planning and ecological constraints.

# Internal and External, Local and Global

Climate variability and change will affect the health and livelihoods of most populations in the coming years, putting the lives and well-being of millions of people at increased risk.

Most climate change adaptation and risk reduction measures require that humans modify existing behaviors or adopt new ones.

Much of our behavior is nonconscious, habitual, and driven by cues in our environment or the way that choices are presented. Moreover, there is a lack of social norms governing how to address climate change in many societies. We are capable of making decisions in a considered, deliberate way, but this happens less often than we assume. When people individually or collectively consider climate science and projections of future change impacts, there can be “psychological distance” related to climate information that can make it seem unreal, intangible, and therefore not urgent.

Human behavior is complex — it often takes a combination of approaches to cause an individual to test, adopt, and sustain behaviors.

The degradation of nature can lead to gender-based violence including sexual assault, domestic violence, forced prostitution and child marriage.
